# 7 Python Documentation

## 7.1 npusearch - Fast regex searching

Source code: /opt/lrl/share/python/npusearch/ (on any Extreme Search<sup>TM</sup> appliance)

The npusearch package provides access for the LRL Extreme Search<sup>TM</sup> appliance. It contains a client class to connect to backends with via redis, as well as a few commandline utilities. This document is the guide to the python API for NPUsearch.

## 7.1.1 NPUGlusterClient

A user must start with an instance of the client class:

 $class\ npuse arch. \textbf{NPUGlusterClient} (gluster\_hosts=None,\ gluster\_volname=None,\ gluster\_args=None,\ gluster\_volname=None,\ gluster\_args=None,\ gluster\_volname=None,\ gluster\_args=None,\ gluster\_args=N$ 

```
redis_host=None, redis_args=None, response_prefix='npusearch:response', registry prefix='npusearch:registry', registry=None, hostname=None)
```

Construct a NPUGlusterClient instance.

If gluster access is desired, <code>gluster\_hosts</code> and <code>gluster\_volname</code> must be passed in (or <code>gluster\_args</code> must contain the keys 'hosts' and 'volname'). Otherwise, no gluster lookups will be preformed, and files must be specified relative to the root of the mounted SSDs themselves, or using absolute paths of format <hostname>:/absolute/path/to/file

If no gluster access is needed and the redis server to use is running on the local machine with default parameters, all arguments are optional.

gluster\_hosts is a string or iterable of strings of gluster servers

gluster\_volname is the name of a gluster volumne for the client to connect to. Extreme Search™ appliances ship with a gluster volume gv0, typically mounted at /mnt/gv0. To look up files in this gluster volume, gluster\_volname="gv0" must be specified.

```
gluster_args is passed into gfapi.Volume(hosts=gluster_hosts, volname=gluster_volname,
**gluster args) when the client mounts to the volume.
```

redis host is the host name of the redis server. If left blank, it defaults to 'localhost'.

redis\_args is passed into redis.Redis(host=redis\_host, \*\*redis\_args) when the client connects to
redis

*response\_prefix* is the prefix to use when generating our response channel. If not provided it defaults to 'npusearch:response'.

registry prefix: see registry below. If not provided it defaults to 'npusearch: registry'.

registry is the registry key to look for backends under as f {registry prefix}: {registry}'.

hostname is the value to use as hostname. If not provided the value returned by hostname (1) is used.

Example: To connect to an Extreme Search<sup>TM</sup> appliance named 'server01' using default configuration, a user could use **NPUGlusterClient** using:

When the user is connecting from 'server01' itself, this can be simplified to

```
>>> client = NPUGlusterClient(gluster_hosts='localhost',
... gluster_volname='gv0')
```

## 7.1.1.1 NPUGlusterClient Functions

## 7.1.1.1.1 scan

NPUGlusterClient.scan(self, exprs, files, registry=None, root=None, timeout=None, callback=None, precompiled=False, return\_type=None, collect=True, compile\_args=None, clean=True, hostname=None, condition=None, \*\*kwargs)

Returns which subset of files match any of the expressions in exprs. scan is the main function for NPUsearch.

Here is a simple scan.

```
>>> client.scan([r'Hello World'], ['examples/*'])
{'pe_usage': 2,
    'matches': [{'matches': [0],
        'overflow': False,
        'path': 'examples/Hello_World.txt',
        'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
'errors': [],
'exceptions': {},
'bytes_scanned': 1253,
'files scanned': 4}
```

**REQUIRED** *exprs* is an iterable of (regular) expressions to scan for. Please see the regex syntax documentation for full details. Alternatively, an iterable of precompiled binary strings can be passed to bypass compilation and speed up search when running the same expressions many times. Please see the *precompiled* argument below for details.

Support for logical combinations of expressions and the ability to match files where "at least n" of the expressions match is supported. To use these functionalities, exprs must be in complex input form.

The complex input syntax is:

```
{ 'type': 'expression',
 'expr': str,
'id': int, #optional
'ref_id': int, #optional
'output id': int} #optional
{'type': 'at_least_n',
 'refs': list of ints,
'n': int,
'id': int, #optional
 'ref_id': int, #optional
'output_id': int, #optional
'maybe_match_id': int} #optional
{ 'type': 'combination',
 'formula': str,
'id': int, #optional
'ref_id': int, #optional
'output_id': int, #optional
'simplify': bool} #optional
```

Please see the <u>complex input format section</u> for full details.

Here is an example using the complex input format. Please see the <u>complex input format section</u> for full details:

```
>>> exprs = [
      {'type': 'expression', 'expr': 'Hello', 'ref_id': 101},
      . . .
. . .
. . .
          'type': 'combination',
. . .
          'formula': '(101 AND 102) OR (103 AND 104)',
. . .
          'output id': 301,
. . .
. . .
      {'type': 'expression', 'expr': 'Hello World', 'output id': 1}
. . .
>>> client.scan(exprs, ['examples/*'])
{'pe usage': 47,
'matches': [{'matches': [1, 201, 301],
  'overflow': False,
  'path': 'examples/Hello World.txt',
  'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
 'errors': [],
 'exceptions': {},
 'bytes_scanned': 1253,
'files_scanned': 4}
```

**REQUIRED** *files* is an iterable of path-like patterns to scan. files may be (and in general should be) expressed as glob patterns as accepted by glob.glob with recursive=True. Any glob containing /../ will be rejected.

When this client has no gluster volume AND no root= is specified, files must be either in brick format or will be taken as relative to every handled SSD mount. This is the ONLY configuration where a scan can be requested against the raw storage.

When the root argument is specified, files and globs must start with the root value, and it will be stripped from the front. This is for the case where files are listed from or globs are written for a mounted volume.

When a gluster volume is mounted, its volname is prepended to every path, which breaks brick paths. npusearch assumes that gluster volumes are backed by brick directories which have the same name as the volume and are located in the root of the mounted partitions.

## Examples:

registry is the registry to use. If not specified the saved registry key will be used.

root is the common root path for the mounted gluster volume. By default, NPUsearch requires the files passed to be relative to the gluster mount point, if gluster is used, or relative to the individual SSD mount points, if not. If root is specified, the paths for the files passed in must start with root. This is useful when using a function such as glob.glob, since the files returned from glob.glob will be relative to the os root as opposed to the gluster volume. If the gluster volume is mounted at /mnt/gv0 (which is default), and the files are gathered from glob.glob, then the argument root='/mnt/gv0' should be passed in.

## Example:

```
>>> client.scan([r'Hello World'], ['/mnt/gv0/examples/*'], root='/mnt/gv0')
{'pe_usage': 2,
'matches': [{'matches': [0],
   'overflow': False,
   'path': '/mnt/gv0/examples/Hello_World.txt',
   'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
'errors': [],
'exceptions': {},
'bytes_scanned': 1253,
'files scanned': 4}
```

timeout is the number of seconds for the NPUGlusterClient to wait for a response from the backends before timing out. By default, a timeout value of None causes scan to never timeout. If timeout is specified and the time limit is met, any results which have already been found will be returned and an exception will be raised.

callback is a function to pass the match results to. NPUsearch supports returning matches and/or errors in a streaming manner. When returning matches, it passes them to the function specified by callback=cb on a background thread as cb(errors=[errors], matches=[matches], progress=progress). The progress can be used to determine how far along the scan is.

Note in the example below how all the results are returned from the backends seperately, and not as one batch. This is because they were all searched by different backends.

```
>>> def callback(errors=None, matches=None, progress=None):
      print(f'These are the errors: {errors!r}.')
       print(f'These are the matches: {matches!r}.')
. . .
       print(f'This is the progress: {progress!r}.\n')
>>> res = client.scan([r'\w+'], ['examples/*'], callback=callback)
These are the errors: [].
These are the matches: [].
This is the progress: {'bytes': 0, 'files': 0}.
These are the errors: [].
These are the matches: [
        'matches': [0],
        'overflow': False,
        'path': 'examples/Hello_World.txt',
        'brick': 'grape2:/mnt/npusearch_10/gv0/examples/Hello_World.txt',
1.
This is the progress: {'bytes': 12, 'files': 1}.
These are the errors: [].
These are the matches: [
        'matches': [0],
        'overflow': False,
        'path': 'examples/NPUsearch.txt',
        'brick': 'grape2:/mnt/npusearch_12/gv0/examples/NPUsearch.txt'
1.
This is the progress: {'bytes': 1095, 'files': 2}.
These are the errors: [].
These are the matches: [
   {
        'matches': [0],
        'overflow': False,
        'path': 'examples/LRL.txt',
        'brick': 'grape2:/mnt/npusearch_14/gv0/examples/LRL.txt',
1.
This is the progress: {'bytes': 1178, 'files': 3}.
These are the errors: [].
These are the matches: [
   {
        'matches': [0],
        'overflow': False,
        'path': 'examples/newline.txt',
        'brick': 'grape2:/mnt/npusearch_2/gv0/examples/newline.txt',
This is the progress: {'bytes': 1253, 'files': 4}.
```

precompiled is a bool representing whether or not compiled input is passed into exprs. If True, the expressions passed in exprs should be compiled NPU binaries, as output by check\_expressions or compiled by hand with /opt/lrl/bin/npusearch\_compiler. See check\_expressions below and the document on command line functionality.

return\_type is the filepath format you want the results returned to you. It is parsed as a npusearch.ReturnType. The default is ReturnType.BRICK|ReturnType.GLUSTER, or ReturnType.BRICK when there is no gluster volume mounted.

When the ReturnType includes ReturnType.BRICK, the match results each include a key "brick" with the brick path of the matching file.

When the ReturnType includes ReturnType.GLUSTER, the match results each include a key "path" with the gluster path of the matching file. If root= was specified, this is prepended to the gluster paths.

When the ReturnType includes ReturnType.CHECKED | ReturnType.GLUSTER, files are checked against the

clients gluster volume to verify that they represent a canonical copy of the file under gluster before being returned. If they do not, then they are dropped.

If ReturnType.GLUSTER is included, no results are returned unless a gluster volume is mounted in the client.

If ReturnType.DEDUP is included, only one file which corresponds to a given path under gluster will be returned, applicable to replicated volumes only.

Users may pass in a string with the name of the ReturnType, e.g "brick|gluster" instead of "ReturnType.BRICK|ReturnType.GLUSTER".

#### Example:

```
>>> client.scan([r'Hello'], ['examples/*'], return_type='brick')
{'pe_usage': 2,
    'matches': [('matches': [0],
        'overflow': False,
        'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
    'errors': [],
    'exceptions': {},
    'bytes_scanned': 1253,
    'files_scanned': 4}
```

collect is a bool representing whether or not results are returned or solely passed into callback. If unspecified or True, matches and errors are collected and returned. If False, matches and errors are ONLY returned via the callback.

Note that none of the files are captured in res:

```
>>> def callback(errors=None, matches=None):
      if errors:
           print('Errors found!')
. . .
       if matches:
. . .
           print(f'Files {[match["path"] for match in matches]} matched!')
>>> res = client.scan([r'\w+'], ['examples/*'], callback=callback, collect=False)
Files ['examples/NPUsearch.txt'] matched!
Files ['examples/Hello World.txt'] matched!
Files ['examples/LRL.txt'] matched!
Files ['examples/newline.txt'] matched!
>>> res
{'pe_usage': 2,
 'matches': [],
 'errors': [],
 'exceptions': {},
 'bytes scanned': 1253,
'files scanned': 4}
```

compile args is a dict of optional args to be passed to precompilation. Useful values include

- "mem limit": limit on compilation mem usage in bytes
- "time\_limit": compilation timeout in bytes
- "compiler": path to an alternate compiler to use
- "checker" : path to an alternate binsize checker to use for calculating pe\_usage

clean is a bool representing whether of not to clean the registry. The default is to clean the registry.

hostname is a string telling scan to only access backends which have bricks on the host provided.

condition is a callable. Supplying condition causes scan to only use backends for which condition (path) returns True for at least one path handled by the backend. A user can search a subset of multiple nodes using condition = lambda p: any(node\_name in p for node\_name in nodes\_to\_search).

## Possible kwargs include:

*chains* is an int which represents the number of chains the backends will use. The value is rounded down to the nearest chain count the backends can support. The default value is the maximum number of chains supported. Limits and default value differ based on hardware; SmartSSDs support a maximum of 12 chains

and Kuona cards support a maximum of 16 chains.

**WARNING**: The time a scan takes is inversely proportional to the number of chains used. Thus setting chains=1 can cause results to return up to 16x slower and take over 6 hours.

**WARNING**: With mixed hardware clusters, when the number of PEs used is over 300, changing this value can lead to some files being scanned and others not scanned, depending on which hardware they are stored. Appropriate exceptions will be returned.

pes is an int which represents the number of PEs in each chain. The value is rounded up to the nearest PE count supported, so that the user can guarentee there are at least pes PEs per chain. Default is 300. Limits differ based on hardware; SmartSSDs support a maximum 3600 PEs and Kuona cards support 4800 PEs.

**WARNING**: The time a scan takes is directly proportional to the number of chains used. Thus setting pes=4800 can cause results to return up to 16x slower and take over 6 hours.

**WARNING**: With mixed hardware clusters, when the number of PEs used is over 3600, changing this value can lead to some files being scanned and others not scanned, depending on which hardware they are stored. Appropriate exceptions will be returned.

## Example:

```
>>> client.scan([str(n) for n in range(500)], ['examples/*'], pes=1500)
{'pe_usage': 1469,
    'matches': [{'matches': [6, 5, 45, 7, 56, 3, 78, 9, 4, 12, 89, 123, 8, 234, 90, 1],
    'overflow': True,
    'path': 'examples/newline.txt',
    'brick': 'server01:/mnt/npusearch_2/gv0/examples/newline.txt'}],
'errors': [],
'exceptions': {},
'bytes_scanned': 1253,
'files_scanned': 4}
```

match\_gaps is an int which tells the backends to run with capacity for at least this many distinct matches. The maximum (and default) value is 16.

files limit is an int which tells each backend to only scan up to this many files. By default, there is no limit.

files\_offset is an int which tells each backend to skip this many files from its expanded globs list. By default, no files will be skipped. Using files\_limit and files\_offset allows a user to "page" through files as opposed to pulling into memory the names of a large number of files. For example, setting files offset=256, files limit=384 will return files 256-384.

decompress is a bool, int, or string which if present specifies auto decompression behavior. if present and True, 1, "on" or "auto" the backends will attempt to autodetect compressed or encoded files using libarchive (3). including nested compression and encoding.

If not present, or if False, 0, or "off" decompression is disabled

Other values for this argument are reserved at the present time.

```
scan returns a dictionary with the keys: 'pe_usage', 'matches', 'errors', and 'exceptions'.
```

The value for 'pe\_usage' is the number of PEs the input expressions or compiled file used. By default, the maximum number of available PEs is 300 (passing in the argument pes or chains changes this). When the number of PEs would be above the number of available PEs, the value for 'pe\_usage' is 0 instead and an exception is noted under 'exceptions'.

The value for 'matches' is a list of dictionaries describing the filepaths which matched. Each dictionary has the keys 'matches' and 'overflow', and a subset of 'path' and 'brick' (depending on the value of return type.).

The keys 'path' and 'brick' designate the location of the matching file. The value is the filepath as a str. See return type for more details. 'path' is only included if return type includes ReturnType.GLUSTER.

'brick' is only included if retury type includes ReturnType.BRICK

The value for 'matches' is a list of ints, which are the indicies of the expressions in exprs which matched. Alternatively, when the complex input format is used, the ints will be the corresponding 'output\_id' for each of the inputs which matched.

The value for 'overflow' is a boolean indicating whether more expressions matched then were able to be reported on 'matches'. A value of False indicates no overflow and the user does not need to take any further action. A value of True means there are more expressions which matched than those reported on 'matches'. This can happen (but is not guaranteed to happen, the hardware details are complex) when the number of matching expressions is greater than match\_gaps (which on current hardware has a maximum value of 16, and defaults to the value passed to the backends when they start).

The value for 'errors' is a list of the filepaths and globs which had errors.

The value for 'exceptions' is a dictionary of exceptions that were raised by the backends. The keys are the name of each backend and the values are a list of the errors that were raised.

Example of multiple matches:

```
>>> client.scan([r'(?i)NPUsearch', r'Hello', r'\w+'], ['examples/*'])
{ 'pe usage': 5,
 'matches': [{'matches': [1, 2],
  'overflow': False,
  'path': 'examples/Hello World.txt',
  'brick': 'server01:/mnt/npusearch 10/gv0/examples/Hello World.txt'},
  {'matches': [2, 0],
   'overflow': False,
  'path': 'examples/LRL.txt',
  'brick': 'server01:/mnt/npusearch_14/gv0/examples/LRL.txt'},
  {'matches': [2, 0],
   'overflow': False,
  'path': 'examples/NPUsearch.txt',
  'brick': 'server01:/mnt/npusearch 9/gv0/examples/NPUsearch.txt'},
 {'matches': [2],
   'overflow': False,
  'path': 'examples/newline.txt',
  'brick': 'server01:/mnt/npusearch_2/gv0/examples/newline.txt'}],
 'errors': [],
 'exceptions': {},
 'bytes_scanned': 1253,
'files_scanned': 4}
```

## Example when there is overflow

```
>>> client.scan([r'Hello World']*20, ['examples/*'])
{'pe_usage': 59,
    'matches': [{'matches': [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13,14, 15],
        'overflow': True,
        'path': 'examples/Hello_World.txt',
        'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
'errors': [],
'exceptions': {},
'bytes_scanned': 1253,
'files_scanned': 4}
```

Some examples of errors:

```
>>> client.scan([str(n) for n in range(500)], ['examples/*'])
{'pe_usage': 0,
  matches': [],
 'errors': [],
 'exceptions': {b'npusearch:request:server01-15-1678816025': [hiredis.ReplyError('FAILED\
 TO LOAD. overfull. 1469 pes required, 300 pes available.')],
 b'npusearch:request:server01-1-1678816025': [hiredis.ReplyError('FAILED\
TO LOAD. overfull. 1469 pes required, 300 pes available.')],
 b'npusearch:request:server01-3-1678816025': [hiredis.ReplyError('FAILED\
 TO LOAD. overfull. 1469 pes required, 300 pes available.')],
 b'npusearch:request:server01-21-1678816025': [hiredis.ReplyError('FAILED\
 TO LOAD. overfull. 1469 pes required, 300 pes available.')]},
 'bytes scanned': 0,
 'files_scanned': 0}
>>> client.scan([r'L(ewis )?R(hodes ?L(abs)?'], ['wiki/00000001.wiki'])
CompileError: Failed to compile "L(ewis)?R(hodes?L(abs)?"
return code: 1
compilation log:
SyntaxError
[{'type': 'expression', 'expr': 'L(ewis )?R(hodes ?L(abs)?', 'ref_id': None, 'output_id': 0, 'flags': ''}]
Unpaired left parenthesis.
```

When there is a CompileError the backends are never engaged. If multiple expressions have CompileErrors, only the first error is thrown. Use <code>check</code> expressions to check every expression for errors.

## 7.1.1.1.2 Backend communication functions

7.1.1.1.2.1 info

NPUGlusterClient.info(self, registry=None, timeout=1, clean=True, hostname=None, condition=None)

This function returns current information about the state of the backends. The arguments registry, clean, hostname, and condition are the same as in scan, while timeout is the amount of time to wait in seconds. It returns a dictionary where the keys are each backend and the values are either an exception or another dictionary with the following key/value pairs (note: these results come directly from the backend, so they are NOT determined by the python version):

status is the current status of the backend.

pes default is the default number of PEs the backend uses.

pes total is the total number of PEs the backend uses.

chains\_default is the default number of chains the backend uses. Note that chains\_default \* pes\_default
= pes\_total.

chains\_supported is a list of ints representing what number of chains are supported.

queue\_size is an int representing how many requests are currently in the queue.

matches default is the default number of match gaps.

matches max is the maximum number of match gaps.

```
>>> client.info()
{'npusearch:request:server01-14-1678816025': {'status': 'Ok',
  'pes default': 300,
  'pes total': 3600,
  'chains_default': 12,
  'chains supported': [1, 3, 6, 12],
  'queue_size': 0,
  'match_gaps_default': 16,
  'match_gaps_max': 16},
  <snip>
 'npusearch:request:server01-17-1678816025': {'status': 'Ok',
  'pes default': 300,
  'pes total': 3600,
  'chains_default': 12,
  'chains_supported': [1, 3, 6, 12],
  'queue_size': 0,
  'match_gaps_default': 16,
 'match_gaps_max': 16}}
```

#### 7.1.1.1.2.2 check

NPUGlusterClient.check(self, registry=None, hostname=None, condition=None, clean=True)

This function checks which backends are currently up and listening. The arguments registry and clean are the same as in scan. Supplying hostname only returns backends which have bricks on the host provided as long as condition is left as None. Supplying condition causes it to only return backends for which condition (path) returns True for at least one path handled by the backend.

It returns a list of the names of all the backends that are currently up and listening.

```
>>> client.check()
[b'npusearch:request:server01-0-1678816025',
b'npusearch:request:server01-1-1678816025',
<snip>
b'npusearch:request:server01-8-1678816025',
b'npusearch:request:server01-9-1678816025']
```

## 7.1.1.1.2.3 quit

NPUGlusterClient.quit(self, registry=None, timeout=1000, hostname=None, condition=None, returncode=0, clean=None)

This function shuts down the NPU backends and returns a dict with whether or not each backend shut down correctly. The arguments are the same as info, with the addition of returncode, which is the return code for the backends to exit with.

This can be useful when managing backends across multiple servers, as quit can be used to selectively shut down backends on some servers but not on others using condition = lambda p: any(server\_name in p for server\_name in servers\_to\_shutdown).

After a few seconds, the backends will come back up.

```
>>> client.quit()
{'npusearch:request:server01-11-1678816025': {'status': '0k'},
    'npusearch:request:server01-21-1678816025': {'status': '0k'},
    'npusearch:request:server01-22-1678816025': {'status': '0k'},
    <snip>
    'npusearch:request:server01-15-1678816025': {'status': '0k'},
    'npusearch:request:server01-4-1678816025': {'status': '0k'}}
>>> client.check()
[]
```

## 7.1.1.1.3 Redis communication functions

7.1.1.3.1 is\_alive

## NPUGlusterClient.is alive(self)

Returns a bool whether or not this instance is listening for pubsub messages.

7.1.1.3.2 start

NPUGlusterClient.start(self)

This function subscribes to pubsub channels.

7.1.1.3.3 stop

NPUGlusterClient.stop(self)

This function unsubscribes from pubsub channels. All outstanding requests are completed with an error status in callback, but not cleared.

7.1.1.1.3.4 clear

NPUGlusterClient.clear(self)

This function unsubscribes from pubsub channels. All outstanding requests are completed with an error status in callback, and then dropped.

## 7.1.1.1.4 File system inspection functions

7.1.1.1.4.1 ls

NPUGlusterClient.ls(self, files, return\_type=ReturnType.BRICK, registry=None, timeout=None, clean=True, root=None, \*\*kwargs)

This function lists all of the files which satisfy the glob format of files (hence the name ls). The arguments are the same as scan, with the options of files\_offset and files\_limit as kwargs. A dictionary is returned with the key/value pairs of 'files': dictionaries with 'brick' and 'path' as selected by return\_type=. 'errors': list of errors.

7.1.1.1.4.2 sizes

NPUGlusterClient.sizes(self, files, return\_type=ReturnType.BRICK, registry=None, timeout=None, clean=True, root=None, \*\*kwargs)

This function is the same as ls, except with each of the entries in the value for 'files' is a dictionary with key/value pairs 'size': int number of bytes, 'brick:' : str and 'path': str, as selected byreturn\_type=An additional key/value pair in the final result is'size': `int number of total bytes.

7.1.1.4.3 stat

NPUGlusterClient.**stat**(self, files, return\_type=ReturnType.BRICK, registry=None, timeout=None, clean=True, root=None, \*\*kwargs)

This function is the same as ls, except that it calls stat on each of the files.

## 7.1.1.2 check\_expressions

npusearch.check\_expressions(self, exprs, compile\_args=None, include\_binary=False)

Takes in exprs and compile args as passed into scan, compiles the exprs, and returns a dictionary with the

results. The key/value pairs of the dictionary are:

exprs is the same as the exprs passed in.

log is a str with all of the error messages which would have been raised when compiling. This includes multiple error messages if multiple entries in exprs have errors.

*pe\_usage* is the number of PEs the compiled expressions would take up on an NPU. It is -1 when there are errors.

binary is only included if include\_binary=True. It is a list of length one with its only entry a binary string which represents the compiled expressions as an NPU binary. The list can then be passed into scan as exprs with the argument precompiled=True set.

Precompiling expressions is useful when a user is running scan multiple times with the same exprs argument. Each invocation of scan calls the compiler by default, so precompiling the expressions allows the user to avoid the overhead of compiling the same expressions multiple times.

check\_expressions never communicates with the NPU backends, only with the compiler (which uses the CPU), so it can be called while other scans are running.

## Examples:

```
>>> npusearch.check expressions(
            r'(?i)celebratory.*neuroscience',
. . .
           r'L(ewis )?R(hodes )?L(abs)?',
. . .
           '(?i)neuromorphic.*computing',
. . .
...)
{'exprs': ['(?i)celebratory.*neuroscience',
 'L(ewis )?R(hodes )?L(abs)?',
 '(?i)neuromorphic.*computing'],
 'log': '',
'pe_usage': 20,
'returncode': 0}
>>> npusearch.check_expressions(
            r'(?i)celebratory.*neuroscience',
. . .
           r'L(ewis )?R(hodes ?L(abs)?',
. . .
            '[Nn]euromorphic.*[Ccomputing',
...)
{'exprs': ['(?i)celebratory.*neuroscience',
 'L(ewis)?R(hodes?L(abs)?',
 '[Nn]euromorphic.*[Ccomputing'],
 'log': "Syntax Error:\
 regex='L(ewis )?R(hodes ?L(abs)?', expr_id=1: Unpaired left parenthesis.\
 regex='[Nn]euromorphic.*[Ccomputing', expr id=2: Unclosed character class.",
 'pe usage': -1,
 'returncode': 1}
>>> config = npusearch.check expressions([r'Hello World'], include binary=True)
>>> client.scan(
       config['binary'],
        ['examples/*'],
. . .
       precompiled=True, # needed when passing in a binary
. . .
...)
{'pe_usage': 2,
 'matches': [{'matches': [0],
   'overflow': False,
   'path': 'examples/Hello World.txt',
  'brick': 'server01:/mnt/npusearch_10/gv0/examples/Hello_World.txt'}],
 'errors': [],
 'exceptions': {},
 'bytes_scanned': 1253,
 'files_scanned': 4}
```

## 7.1.1.3 ReturnType

class npusearch.ReturnType(enum.Flag)

Used in the return\_type argument in scan. Values are BRICK, GLUSTER, and CHECKED. See scan for more details.

## 7.2 More Advanced Examples

## 7.2.1 Multi-node Systems

In these examples, the user has two servers named box01 and server01 and gluster volume gv3 set up across both servers.

All of these are valid ways to instantiate the client so that it connects to gluster sucessfully.

An example scan demonstrates data returned from different servers:

```
>>> client.scan([r'^[0-5]$'], ['test/*'], return type='both')
{'pe_usage': 8,
 'matches': [{'matches': [0],
  'overflow': False,
   'path': 'test/0',
   'brick': 'server01:/mnt/npusearch_8/gv3/test/0'},
  {'matches': [0],
   'overflow': False,
  'path': 'test/4',
  'brick': 'box01:/mnt/npusearch_3/gv3/test/4'},
  {'matches': [0],
   'overflow': False,
  'path': 'test/2',
  'brick': 'box01:/mnt/npusearch_8/gv3/test/2'},
  {'matches': [0],
   'overflow': False,
  'path': 'test/3'
  'brick': 'box01:/mnt/npusearch 8/gv3/test/3'},
  {'matches': [0],
   'overflow': False,
  'path': 'test/1',
   'brick': 'box01:/mnt/npusearch 20/gv3/test/1'},
  {'matches': [0],
   'overflow': False,
   'path': 'test/5',
  'brick': 'server01:/mnt/npusearch_5/gv3/test/5'}],
 'errors': [],
 'exceptions': {}}
```

A user can shut down one set of backends and check to see that the other is still up:

```
>>> client.quit(hostname='server01')
{'npusearch:request:server01-3-1678814900': {'status': 'Ok'},
    'npusearch:request:server01-21-1678814900': {'status': 'Ok'},

<snip>
    'npusearch:request:server01-7-1678814900': {'status': 'Ok'},
    'npusearch:request:server01-1-1678814900': {'status': 'Ok'}}
>>> client.check()
[b'npusearch:request:box01-0-1678814898',
    b'npusearch:request:box01-1-1678814898',
    b'npusearch:request:box01-8-1678814898',
    b'npusearch:request:box01-8-1678814898',
    b'npusearch:request:box01-9-1678814898']
```

## 7.2.2 Forgoing Gluster

Gluster is not needed to run scans, only to get the final path. In this example, a user can run the same search as above without touching gluster:

```
>>> no gluster = NPUGlusterClient()
>>> no_gluster.scan([r'^[0-5]$'], ['gv3/test/*']) #gv3 (or *) needed on filepath
{ 'pe_usage': 8,
 'matches': [{'matches': [0],
   'overflow': False,
   'brick': 'box01:/mnt/npusearch_3/gv3/test/4'},
  {'matches': [0],
   'overflow': False,
  'brick': 'server01:/mnt/npusearch_8/gv3/test/0'},
  {'matches': [0],
   'overflow': False,
  'brick': 'box01:/mnt/npusearch 20/gv3/test/1'},
  {'matches': [0],
   'overflow': False,
  'brick': 'box01:/mnt/npusearch_8/gv3/test/2'},
  {'matches': [0],
   'overflow': False,
  'brick': 'box01:/mnt/npusearch_8/gv3/test/3'},
  {'matches': [0],
   'overflow': False,
  'brick': 'server01:/mnt/npusearch_5/gv3/test/5'}],
 'errors': [],
 'exceptions': {}}
```

Note that asking for the gluster path to be returned raises an error:

```
>>> no_gluster.scan([r'^[0-5]$'], ['gv3/test/*'], return_type='gluster')
ValueError
<snip>
ValueError: return type has ReturnType.GLUSTER but no gluster volume mounted. \
return type is ReturnType.GLUSTER
```

In this example, although the client did not talk to gluster, the files for gv3 were still placed using gluster. Gluster is not needed to place files, however if the files are not distributed uniformly across the storage, then the performance of scan can get substantially worse.

Here is an example where two files were placed manually without gluster on different drives:

```
>>> no_gluster.scan([r'(?i)gluster freee+'], ['no_gluster/*'])
{'pe_usage': 2,
    'matches': [{'matches': [0],
        'overflow': False,
        'brick': 'box01:/mnt/npusearch_20/no_gluster/gluster_free.txt'},
        {'matches': [0],
        'overflow': False,
        'brick': 'server01:/mnt/npusearch_10/no_gluster/gluster_free.txt'}],
    'errors': [],
    'exceptions': {}}
```

The user can specify which drives to search or alternatively which hostnames to search. This can be done when gluster is connected as well, however a user would generally not leave drives under a gluster cluster out

of a scan unless the user knows exactly which drives specific files live on.

```
>>> prefixes = [f'server01:/mnt/npusearch_{i}' for i in range(24)]
>>> no_gluster.scan(
       [r'(?i)gluster freee+'],
        [f'{prefix}/no_gluster/*' for prefix in prefixes],
...)
{ 'pe usage': 2,
 'matches': [{'matches': [0],
  'overflow': False,
  'brick': 'server01:/mnt/npusearch 10/no gluster/gluster free.txt'}],
 'errors': [],
 'exceptions': {}}
>>> no_gluster.scan([r'(?i)gluster freee+'], ['no_gluster/*'], hostname='box01')
{'pe_usage': 2,
 'matches': [{'matches': [0],
  'overflow': False,
  'brick': 'box01:/mnt/npusearch_20/no_gluster/gluster_free.txt'}],
 'errors': [],
 'exceptions': {}}
 >>> client.scan([r'^[0-5]$'], ['test/*'], hostname='server01')
 {'pe_usage': 8,
 'matches': [{'matches': [0],
   'overflow': False,
  'path': 'test/0',
  'brick': 'server01:/mnt/npusearch_8/gv3/test/0'},
  {'matches': [0],
   'overflow': False,
  'path': 'test/5',
  'brick': 'server01:/mnt/npusearch_5/gv3/test/5'}],
 'errors': [],
'exceptions': {}}
```
